October 13, 2006

Abstract

In this paper, a new method for constructing confidence intervals for $\sigma^2_\alpha$, $\sigma^2_\varepsilon$ and the intraclass correlation $\rho = \sigma^2_\alpha/(\sigma^2_\alpha + \sigma^2_\varepsilon)$ in a two component mixed effects linear model is proposed. This method is based on an extension of R. A. Fisher's fiducial argument. A simulation study is conducted to compare the resulting interval estimates with other competing confidence interval procedures from the literature. Our results demonstrate that the proposed fiducial intervals have satisfactory performance in terms of coverage probability. In addition these intervals have shorter average confidence interval lengths overall. We also prove that these fiducial intervals have asymptotically exact frequentist coverage probability. The computations for the proposed procedures are illustrated using examples from animal breeding applications.

Keywords: Fiducial Density, Fiducial Generalized Confidence Interval (FGCI), Unbalanced One-Way Random Effects Model, Variance Component.

1 Introduction

Random effects and mixed effects linear models are useful in applications that require accounting for components of variability arising from multiple sources. For example, in animal breeding studies, mixed linear models with two variance components are often used. One variance component accounts for genetic variability and the other accounts for variability due to environmental factors. In industrial applications where one is interested in understanding process variability mixed models with multiple variance components are used to account for variability due to operators, due to batches of raw material, due to machine differences, due to measurement errors, and so on. In such situations it is of interest to estimate the components of variance and provide lower and upper confidence bounds for them.

Confidence intervals for variance components have been an important topic of research for over 70 years. Interestingly, the first published work on interval estimation for the between groups variance component in the standard one-way normal random model is by R. A. Fisher (1935) who gave a solution to this problem using his then new method of fiducial argument. Bross (1950) provided further computational details for the fiducial approach and informally compared it with
approximate frequentist methods available at the time. Numerous subsequent articles have been written on this topic by many authors. See for instance, Green (1954), Huitson (1955), Graybill et al. (1956), Welch (1956), Healy (1961, 1963), Williams (1962), Broemeling (1969), Burdick and Sielken (1978), Venables and James (1978), Jeyaratnam and Graybill (1980), Graybill and Wang (1980), Seely (1980), Burdick and Graybill (1984), Harville and Fenech (1985), Wild (1981), among others. Most of this work is devoted to developing exact or approximate confidence intervals for specified linear functions of variance components or their ratios. Some of the work was carried out in the context of inference on a heritability coefficient in animal breeding contexts. Healy (1963), Venables and James (1978), and Wild (1981) consider fiducial approaches to the problem in the case of balanced data.

Our focus in this paper is on two variance component unbalanced normal mixed linear models. A fiducial solution to the interval estimation problem in this context is not currently available. Here we develop such a fiducial solution and demonstrate via a simulation study that the resulting procedure has better overall frequentist performance than competing methods. We also establish the asymptotic exactness of the coverage probability of fiducial intervals for variance components of interest.

More specifically, let \( Y \) denote a \( N \times 1 \) vector of observable random variables. Suppose \( Y \) has a distribution described by the following mixed linear model with two variance components

\[
Y = X\beta + Zu + \varepsilon
\]

where \( X \) and \( Z \) are known incidence matrices of sizes \( N \times p \) and \( N \times a \), respectively, \( \beta \) is a \( p \times 1 \) vector of unknown parameters, \( u \sim N(0, \sigma_\alpha^2 A) \) is a \( a \times 1 \) vector of random effects, \( \varepsilon \sim N(0, \sigma_\varepsilon^2 I_N) \) is the error vector of size \( N \times 1 \), and \( u \) and \( \varepsilon \) are independent. Without loss of generality we assume \( \text{rank}(X) = p \). Also \( A \) is a known matrix often referred to as a relationship matrix in animal breeding context since it describes the degree to which the elements \( u_1, \ldots, u_a \) of the vector \( u \) covary. For example, if the elements \( u_1 \) and \( u_2 \) of \( u \) are the (additive) genetic effects corresponding to a parent and an offspring, respectively, then \( \text{Cov}(u_1, u_2) = \sigma_\alpha^2 / 2 \) (Falconer, 1989). Note that, when the standard unbalanced one-way random effects model given by

\[
Y_{ij} = \mu + u_i + \varepsilon_{ij}, \quad i = 1, \ldots, a; \quad j = 1, \ldots, n_i,
\]

is written in matrix form the matrix \( X \) is simply \( I_N \), a column vector whose elements are all equal to one, \( Z = \text{diag}(I_{n_1}, \ldots, I_{n_a}) \) is a block diagonal matrix whose \( i^{th} \) block is \( I_{n_i} \), and \( A \) is \( I_N \). Here \( I_r \) denotes the \( r \times r \) identity matrix. Under the model in (1), \( E[Y] = X\beta \) and \( \text{Var}[Y] = V = \sigma_\alpha^2 ZAZ^T + \sigma_\varepsilon^2 I_N \). In this paper, we focus on constructing confidence intervals for the variance component \( \sigma_\alpha^2 \), \( \sigma_\varepsilon^2 \) and the ratio \( \rho = \sigma_\alpha^2 / (\sigma_\alpha^2 + \sigma_\varepsilon^2) \). In the special case of a one-way random effects model, \( \sigma_\alpha^2 \) is the between-groups variance component and \( \rho \) is the intraclass correlation coefficient. Our proposed methods follow the fiducial generalized confidence interval (FGPQ) procedures discussed in Hannig et al. (2006) and the generalizations of the fiducial method given in Hannig (2006).

The paper is organized as follows. Section 2 provides a brief review of published confidence interval procedures for \( \sigma_\alpha^2 \), \( \sigma_\varepsilon^2 \) and \( \rho \). In Section 3 we outline the fiducial method for obtaining confidence intervals for general situations. We then apply this method to derive fiducial confidence
intervals for $\sigma^2_\alpha$, $\sigma^2_\epsilon$ and $\rho$. Our procedure is applicable to the two component mixed model given in (1). We compare our proposed procedures with competing methods described in Section 2 using a simulation study. Details of the simulation study are described in Section 4 along with a discussion of the simulation results. Tables containing numerical results from the simulation study are given in the Appendix. In Section 5 we consider some data examples using previously published data and illustrate how our proposed procedures are applied. Asymptotic exactness of the proposed fiducial intervals is proved in Section 6. Finally, we conclude with summary discussions in Section 7.

2 Discussion of Published Confidence Intervals for Two Component Mixed Models

This section provides an overview of various published confidence intervals for $\sigma^2_\alpha$, $\sigma^2_\epsilon$, and $\rho = \sigma^2_\alpha/(\sigma^2_\alpha + \sigma^2_\epsilon)$ in a two-component mixed model. First we discuss the unbalanced one-way random effects model.

One-way unbalanced random effects model

Here we consider the unbalanced one-way random effects model, see Equation (2), which is a special case of (1). The standard ANOVA table for this model is shown in Table 1 where the following notation is used.

$$
\bar{Y}_{i*} = \frac{\sum_{j=1}^{n_i} Y_{ij}}{N}, \quad \bar{Y}_{**} = \frac{\sum_{i=1}^{a} n_i \bar{Y}_{i*}}{N}, \quad SS_1 = \sum_{i=1}^{a} n_i (\bar{Y}_{i*} - \bar{Y}_{**})^2,
$$

$$
SS_2 = \sum_{i=1}^{a} \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_{i*})^2, \quad N = \sum_{i=1}^{a} n_i, \quad \text{and} \quad n_0 = \frac{N - \sum_{i=1}^{a} n_i^2}{a - 1}.
$$

When $n_i$ are all equal, the one-way random effects model is said to be balanced. In this case we write $n_i = n$. It follows that, in the balanced case $n_0 = n$, and $SS_1/\theta_1$ and $SS_2/\theta_2$ are independent chi-squared random variables with $a - 1$ and $N - a$ degrees of freedom, respectively. It is well known that, in the balanced one-way random effects model, exact confidence intervals are available for $\sigma^2_\epsilon$, $\sigma^2_\alpha/\sigma^2_\epsilon$ and $\rho$. An exact confidence interval for the between group variance $\sigma^2_\alpha$ is not available even in the balanced case. Approximate confidence intervals for $\sigma^2_\alpha$ include the well-known Tukey-Williams
(Tukey (1951), Williams (1962)) methods and a host of other methods including the method based on Satterthwaite’s (1946) approximation. See Burdick and Graybill (1992) for details.

In the case of an unbalanced design, $SS_1$ and $SS_2$ are still independent and $SS_2/\sigma^2$ still has a chi-squared distribution with $N - a$ degrees of freedom, but $SS_1/\theta_1$ does not have a chi-squared distribution unless $\sigma^2_\alpha = 0$ (Burdick and Graybill, 1992).

2.1 Confidence intervals for $\sigma^2_\alpha$ in an unbalanced one-way random effects model

Several methods are available in the literature for constructing approximate confidence intervals for $\sigma^2_\alpha$ in the unbalanced one-way random effects model. Five different confidence interval procedures for $\sigma^2_\alpha$ that have previously appeared in the literature are discussed below.

Burdick-Graybill (BG) confidence interval

In an unbalanced design, $SS_1/\theta_1$ has a chis-squared distribution if and only if $\sigma^2_\alpha = 0$. If it is known that $\sigma^2_\alpha$ is close to zero, then treating $SS_1/\theta_1$ as a chi-squared random variable may be appropriate. Using this idea, Burdick and Graybill (1992) developed an approximate confidence interval for $\sigma^2_\alpha$ based on the reasoning that $SS_1/\theta_1$ has, approximately, a chi-squared distribution with $a - 1$ degrees of freedom when $\sigma^2_\alpha$ is close to zero. They obtained this approximate confidence interval by appropriately modifying the corresponding confidence interval in balanced case. The resulting approximate two-sided $(1 - \alpha)100\%$ confidence interval is given by

$$\left[ \max \left( \frac{S^2_1 - S^2_2 - \sqrt{V_L}}{n_0}, 0 \right), \ max \left( \frac{S^2_1 - S^2_2 + \sqrt{V_U}}{n_0}, 0 \right) \right]$$

where

$$V_L = G^2 S^4_1 + H^2 S^4_2 + G_{12} S^2_1 S^2_2, \quad V_U = H^2 S^4_1 + G^2 S^4_2 + H_{12} S^2_1 S^2_2,$$

$$G_1 = 1 - \frac{1}{F_{1-a/2,a-1,\infty}}, \quad G_2 = 1 - \frac{1}{F_{1-a/2,N-a,\infty}},$$

$$H_1 = \frac{1}{F_{a/2,a-1,\infty}} - 1, \quad H_2 = \frac{1}{F_{a/2,N-a,\infty}} - 1,$$

$$G_{12} = \frac{(F_{1-a/2,a-1,N-a} - 1)^2 - G^2}{F_{1-a/2,a-1,N-a} - H^2},$$

$$H_{12} = \frac{(1 - F_{a/2,a-1,N-a})^2 - H^2 F^2_{a/2,a-1,N-a} - G^2}{F_{a/2,a-1,N-a}}$$

and $F_{\alpha;v_1,v_2}$ represents the $\alpha$-quantile of the $F$-distribution with $v_1$ and $v_2$ degrees of freedom. Since this procedure is based on the assumption that $\sigma^2_\alpha$ is close to zero, it might result in very liberal intervals when $\sigma^2_\alpha$ is far from zero (Burdick and Graybill, 1992).
Thomas-Hultquist (TH) confidence interval

Thomas and Hultquist (1978) derived an approximate pivotal quantity for $\theta_1$ that can be used for constructing confidence intervals for $\sigma_\alpha^2$ in the unbalanced one-way random effects model. This quantity is

$$SS_3 = \frac{a}{\sum_{i=1}^a \left( Y_i - \frac{1}{a} \sum_{i=1}^a Y_i \right)^2 }, \quad \theta_3 = \sigma_\alpha^2 + \frac{\sigma_\epsilon^2}{\tilde{n}}, \quad \text{and } \tilde{n} = \frac{a}{\sum_{i=1}^a (1/n_i)}.$$

We define $S_3^2 = SS_3/(a - 1)$. Note that $SS_3$ is the unweighted sum of squares of the treatment means and $\tilde{n}$ denotes the harmonic mean of $n_i$ values. Thomas and Hultquist (1978) showed that the moment generating function of $SS_3/\theta_3$ approaches that of a chi-squared random variable with $a - 1$ degrees of freedom as all $n_i$ approach a constant value or infinity, or if the ratio $\eta = \sigma_\alpha^2/\sigma_\epsilon^2$ approaches infinity. Furthermore, $SS_3$ is independent of $SS_2$. Therefore, $(SS_3/\theta_3)/(SS_2/\theta_2)$ has an approximate $F_{a-1,N-a}$ distribution. Using these facts and modifying the Tukey-Williams confidence interval formula for $\sigma_\alpha^2$ developed for the balanced case, Thomas and Hultquist (1978) proposed the following approximate two-sided $(1 - \alpha)100\%$ confidence interval for $\sigma_\alpha^2$

$$\left[ \tilde{n}SS_3 - (a - 1)S_2^2F_{1-a/2,a-1,N-a}^{1-\alpha/2}, \tilde{n}SS_3 - (a - 1)S_2^2F_{1-a/2,a-1,N-a}^{\alpha/2} \right],$$

where $\chi^2_{a,v}$ represents the $\alpha$-quantile of the chi-squared distribution with $v$ degrees of freedom. Results of their simulation study indicated that $SS_3/\theta_3$ is not well approximated by a chi-squared random variable when $\eta < 0.25$ and the design is extremely unbalanced. In these cases, the confidence interval in (3) can be quite liberal.

Burdick-Eickman (BE) confidence interval

Williams (1962) constructed an interval for $\sigma_\alpha^2$ in the balanced one-way random effects model by solving for the intersection of exact $(1 - \alpha)100\%$ confidence intervals on $\sigma_\epsilon^2 + n\sigma_\alpha^2$ and the ratio $\eta$. Burdick and Eickman (1986) followed this strategy and combined approximate intervals for $\theta_3$ and $\eta$. The approximate $(1 - \alpha)100\%$ confidence interval for $\theta_3$ they used is based on the Thomas-Hultquist (1978) approximation, and is given by

$$\left[ \frac{SS_3}{\chi_{1-a/2,a-1}^2}, \frac{SS_3}{\chi_{\alpha/2,a-1}^2} \right].$$

The approximate $(1 - \alpha)100\%$ confidence interval on $\eta$ they used is the one developed by Burdick et al. (1986). This interval is $[L_{BM}, U_{BM}]$ where

$$L_{BM} = \max\left(0, \frac{S_3^2}{S_2^2F_{1-a/2,a-1,N-a}^{\eta/\min\{n_1, \ldots, n_a\}}}, \frac{1}{\max\{n_1, \ldots, n_a\}} \right),$$

$$U_{BM} = \max\left(0, \frac{S_3^2}{S_2^2F_{1-a/2,a-1,N-a}^{\eta/\min\{n_1, \ldots, n_a\}}}, \frac{1}{\max\{n_1, \ldots, n_a\}} \right).$$
The interval in (5) has a confidence coefficient at least as great as $1 - \alpha$. By finding the intersection region of (4) and (5), Burdick and Eickman arrived at an approximate two-sided $(1 - \alpha)100\%$ confidence interval for $\sigma^2_\alpha$. This interval is

$$\left[\frac{\tilde{n}L_{BM}}{1 + \tilde{n}L_{BM}} \frac{SS_3}{\chi^2_{1-\alpha/2,a-1}}, \frac{\tilde{n}U_{BM}}{1 + \tilde{n}U_{BM}} \frac{SS_3}{\chi^2_{\alpha/2,a-1}}\right].$$  \hspace{1cm} (6)

The confidence coefficient of the interval in (6) is at least $1 - \alpha$.

**Hartung-Knapp (HK) confidence interval**

In the unbalanced one-way random effects model Wald (1940) showed that the quantity $SS_4$ defined by

$$SS_4 = \sum_{i=1}^{a} w_i \left( \overline{Y}_{i*} - \frac{\sum_{i=1}^{a} w_i \overline{Y}_{i*}}{\sum_{i=1}^{a} w_i} \right)^2$$

where $w_i = n_i/(1 + \eta n_i)$ is a pivotal quantity for $\eta = \sigma^2_\alpha/\sigma^2_\varepsilon$. Specifically, $SS_4/\sigma^2_\varepsilon$ follows chi-squared distribution with $a - 1$ degrees of freedom. Furthermore, $SS_4$ and $SS_2$ are independent. Therefore, letting $S^2_4 = SS_4/(a - 1)$, it follows that

$$R(\eta) = \frac{S^2_4}{S^2_2} \sim F_{a - 1, N - a}$$

and an exact confidence interval for $\eta$ may be obtained from an interval for $R(\eta)$. Wald (1940) showed that $SS_4$ is a strictly monotonic decreasing function in $\eta$, so the bounds of a $100(1 - \alpha)\%$ confidence interval for $\eta$ are given as the unique solutions to the equations

$$R(\eta) = F_{1 - \alpha/2,a-1,N-a},$$
$$R(\eta) = F_{\alpha/2,a-1,N-a}. \hspace{1cm} (7)$$

Hartung and Knapp (2000) considered the solutions, $\eta_L$, $\eta_U$, to equations (7) and used these to construct an approximate two-sided $(1 - \alpha)100\%$ confidence interval for $\sigma^2_\alpha$. Their interval is given by

$$[S^2_2\eta'_L, S^2_2\eta'_U],$$

where

$$\eta'_L = \begin{cases} \eta_L & \text{if } 0 \leq \eta_L \leq R(0) \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \eta'_U = \begin{cases} \eta_U & \text{if } 0 \leq \eta_U \leq R(0) \\ 0 & \text{otherwise} \end{cases}.$$

It is important to note that the four interval procedures discussed above apply only for the one-way random model. They do not apply to the general two-component mixed model in (1).
2.2 Confidence intervals for $\sigma^2_\alpha$ in a two variance components mixed model

Arendacká (2005) proposed a method that is applicable in some instances of the model in (1). We describe her method next. Before doing so, we review some well known results concerning minimal sufficient statistics for the mixed model in (1).

Let $H$ be a $N \times (N - p)$ matrix such that $HH^T = I_N - X(X^TX)^{-1}X^T$ and $H^TH = I_{N-p}$. Using the fact that $Y \sim N(X\beta, \sigma^2_\varepsilon I_N + \sigma^2_\alpha ZAZ^T)$, it follows that $H^TY \sim N(0, \sigma^2_\varepsilon I_N - p + \sigma^2_\alpha G)$ (8)

where $G = H^T Z AZ^T H$. Let $\lambda_1, \ldots, \lambda_d \geq 0$ be the distinct eigenvalues of $G$ having multiplicities $r_1, \ldots, r_d$, respectively. Let $P = [P_1, \ldots, P_d]$ be a $(N-p) \times (N-p)$ orthogonal matrix such that $P^T GP = \text{diag}(\lambda_1 1_{r_1}^T, \ldots, \lambda_d 1_{r_d}^T)$, where $P_i$ corresponding to $\lambda_i$ is of size $(N-p) \times r_i$. Define $V_i = Y^T H P_i P_i^T H^T Y$, $i = 1, \ldots, d$.

Olsen et al. (1976) showed that $(V_1, \ldots, V_d)$ is minimal sufficient for $(\sigma^2_\varepsilon, \sigma^2_\alpha)$ under (8). Furthermore, $U_i = \frac{V_i}{\lambda_i \sigma^2_\alpha + \sigma^2_\varepsilon} \sim \chi^2_{r_i}$, $i = 1, \ldots, d$, (10)

and $U_i$s’ are mutually independent.

Note that, when $\lambda_d$ is zero, a pure error estimate of $\sigma^2_\varepsilon$ is given by $V_d/r_d$. An exact $100(1-\alpha)$% confidence interval for $\sigma^2_\varepsilon$ exists and is given by

$$\left[\frac{V_d}{\chi^2_{1-\alpha/2; r_d}}, \frac{V_d}{\chi^2_{\alpha/2; r_d}}\right]$$

(11)

We refer to the interval in (11) as EXACT (EX) confidence interval for $\sigma^2_\varepsilon$. When $\lambda_d > 0$ a pure error estimate of $\sigma^2_\varepsilon$ is not available. In particular, an exact confidence interval for $\sigma^2_\varepsilon$ is unavailable.

Arendacká (Ar) confidence interval

Arendacká (2005) considered the special case of $\lambda_d = 0$ and constructed a confidence interval for $\sigma^2_\alpha$ using generalized test variables and generalized p-values. For a discussion of generalized p-values, see Weerahandi (1991). Arendacká showed that the quantity $T$ defined by

$$T = \sum_{i=1}^{d-1} \left( U_i - \frac{v_i U_d}{v_d + \lambda_i \sigma^2_\alpha U_d} \right) ,$$

(12)

is a generalized test variable, where $(v_1, \ldots, v_d)$ is a realization of $(V_1, \ldots, V_d)$. She further defined the function

$$\pi_T(v_1, \ldots, v_d, \sigma^2_\alpha) = \int_0^\infty \left( 1 - \frac{v_1 u}{v_d + \lambda_1 \sigma^2_\alpha u} \right) f_{U_d}(u) du,$$
where $W = \sum_{i=1}^{d-1} U_i$ and $f_{U_d}(u)$ is the p.d.f. of $U_d$. She showed that

$$L_{BA} \leq \sigma^2_\alpha \leq U_{BA}$$

is a generalized confidence interval for $\sigma^2_\alpha$, where $L_{BA}$ and $U_{BA}$ are obtained by solving the equations

$$\pi_T(v_1, \ldots, v_d, L_{BA}) = \alpha/2, \quad \text{and} \quad \pi_T(v_1, \ldots, v_d, U_{BA}) = 1 - \alpha/2.$$ 

In particular, $[L_{BA}, U_{BA}]$ has coverage probability approximately $(1 - \alpha)$. It is worth noting that Arendacká’s method is closely related to the generalized pivotal quantity for $\sigma^2_\alpha$ derived in Iyer et al. (2004) in an unbalanced one-way random model with heterogeneous variances.

Arendacká (2005) also considered three other test variables based on the results in Zhou and Mathew (1994). Her simulation study showed that all the test variables perform equally well in terms of empirical coverages. But when comparing the average lengths of the intervals, the test variable $T$ in (12) performed better overall than the other three test variables. Thus we use the interval in (13) for comparing with our proposed fiducial method.

### 2.3 Confidence intervals for $\sigma^2_\epsilon$ in a two variance components mixed model

As mentioned earlier, an exact confidence interval for $\sigma^2_\epsilon$ is available when $\lambda_d = 0$, i.e., a pure error estimate of $\sigma^2_\epsilon$ is available. However, for the case $\lambda_d > 0$, to our knowledge, no confidence interval procedure has been proposed in the literature for $\sigma^2_\epsilon$. Here we propose a fiducial interval estimate for $\sigma^2_\epsilon$ that appears to have satisfactory coverage properties. The fiducial approach is discussed in Section 3.

### 2.4 Confidence intervals for $\rho$ in a two variance components mixed model

In many applications the quantity $\rho = \sigma^2_\alpha / (\sigma^2_\alpha + \sigma^2_\epsilon)$ is of interest. For example, in plant and animal breeding, $\rho$ represents the proportion of the total variance that is explainable by additive genetic effects. It is often referred to as the heritability of the trait under study. Burch and Iyer (1997) proposed a class of confidence intervals for $\rho$ under the general two-component mixed effects linear model in (1). We describe their method below.
Burch and Iyer (BI) confidence intervals for \( \rho \)

Burch and Iyer (1997) proposed a method to construct an exact confidence interval on \( \rho \) based on a class of pivotal quantities \( R_k, k = 1, \ldots, d - 1 \), given by

\[
R_k = \frac{\sum_{i=k+1}^{d} \frac{V_i}{1 + \rho(\lambda_i - 1)}}{\sum_{i=k+1}^{d} r_i} \bigg/ \frac{\sum_{j=1}^{k} \frac{V_j}{1 + \rho(\lambda_j - 1)}}{\sum_{j=1}^{k} r_j}.
\]

(14)

They observed that \( R_k \sim F \left( \sum_{i=k+1}^{d} r_i, \sum_{j=1}^{k} r_j \right) \) for each \( k = 1, \ldots, d - 1 \). The pivotal quantity in (14) is a monotone decreasing function of \( \rho \). Therefore, a confidence interval for \( \rho \) can be obtained by numerically inverting suitable probability limits for the pivotal quantity \( R_k \). An exact \((1 - \alpha)100\%\) confidence region for \( \rho \) is given by the set

\[
\left\{ \rho \in [0, 1) : \frac{\sum_{i=k+1}^{d} \frac{V_i}{1 + \rho(\lambda_i - 1)} / \sum_{i=k+1}^{d} r_i}{\sum_{j=1}^{k} \frac{V_j}{1 + \rho(\lambda_j - 1)} / \sum_{j=1}^{k} r_j} \leq F_{1-\alpha/2} \right\},
\]

where \( F_{\alpha/2} \) and \( F_{1-\alpha/2} \) are the \( 100(\alpha/2) \)–percentile and \( 100(1 - \alpha/2) \)–percentile of the \( F \) distribution having numerator and denominator degrees of freedom equal to \( \sum_{i=k+1}^{d} r_i \) and \( \sum_{j=1}^{k} r_j \), respectively. Let \( L \) denote the infimum of this set and \( U \) the supremum. Then \([L, U]\) is a confidence interval for \( \rho \) with confidence coefficient equal to \((1 - \alpha)\). Note that there are \( d - 1 \) possible versions of the pivotal quantity \( R_k \) and consequently \( d - 1 \) possible confidence intervals. Burch and Iyer (1997) showed that a confidence interval for \( \rho \) obtained from the pivotal quantity \( R_k \) is locally unbiased if the numerator degrees of freedom for \( R_k \) is equal to the denominator degrees of freedom, i.e., \( \sum_{i=k+1}^{d} r_i = \sum_{j=1}^{k} r_j \). When such a \( k \) does not exist, they suggest using a \( k \) for which the numerator degrees of freedom, \( \sum_{i=k+1}^{d} r_i \), and the denominator degrees of freedom \( \sum_{j=1}^{k} r_j \), are as close to each other as possible. We refer to the resulting interval as BI confidence interval.

We will compare our proposed fiducial interval for \( \rho \) with the BI intervals.

3 Fiducial Intervals for \( \sigma^2_\alpha \), \( \sigma^2_x \) and \( \rho \)

It is worth noting that generalized confidence intervals such as those proposed by Arendacká (2005) are closely related to fiducial intervals. This connection between generalized inference and fiducial inference is discussed in detail by Hannig et al. (2006). They also provide a recipe for constructing fiducial intervals when \( \mathbf{X} \) has a continuous distribution. Hannig (2006) generalizes this to arbitrary distributions. We use the term \textit{weak fiducial inference} to emphasize the fact that the version of
fiducial inference discussed in Hannig et al. (2006) and Hannig (2006) is a generalization of R. A. Fisher’s fiducial argument.

In this section we describe fiducial interval (FI) procedures for \( \sigma_\alpha^2 \), \( \sigma_\varepsilon^2 \) and \( \rho \) that are applicable under the general two-component mixed model in (1). The intervals we propose are obtained using the fiducial method described in Hannig et al. (2006) and Hannig (2006). We first briefly describe weak fiducial inference.

3.1 The Fiducial approach

Let \( X \) be a (possibly discrete) random vector with a distribution indexed by a (possibly vector) parameter \( \xi \in \Xi \). Hannig (2006) defines a weak fiducial distribution for \( \xi \) as follows. Assume that \( X \) has a structural representation given by \( X = G(U, \xi) \) where \( U \) is a uniform \((0, 1)\) random variable and \( G \) is a jointly measurable function of \( U \) and \( \xi \). Let \( R(x, u) \) be a set-valued function defined by

\[
R(x, u) = \{ \xi : x = G(u, \xi) \}
\]

The set \( \{ \xi : x = G(u, \xi) \} \) may be empty, may consist of a single element, or, when the distribution of \( X \) is not continuous, may consist of more than one element (possibly uncountably many elements). The function \( R(X, U) \) may be viewed as an inverse of the function \( G \). Here \( G \) defines \( u \) as an implicit function of \( \xi \) and \( x \) is regarded as fixed. Finally, for any measurable set \( S \), let \( V(S) \) denote a random variable with support \( \overline{S} \), where \( \overline{S} \) is the closure of \( S \). Hannig (2006) defined a weak fiducial distribution of \( \xi \) as a conditional distribution of \( V(R(x, U^*)) \) given \( R(x, U^*) \neq \emptyset \). Here \( x \) is the observed value of \( X \) and \( U^* \) is an independent copy of \( U \). Note, without loss of generality, that \( U \) could be taken as any random variable or random vector whose distribution is free of unknown parameters, since any such distribution can be generated starting from a uniform \([0, 1]\) variate.

In the next subsection we apply the fiducial method to construct a confidence interval for \( \sigma_\alpha^2 \).

3.2 A Fiducial confidence interval for \( \sigma_\alpha^2 \)

We first derive a weak fiducial distribution for \( \sigma_\alpha^2 \) and use it to construct confidence intervals for it. We begin with the statistics \( Q_i = V_i / r_i, \ i = 1, \ldots, d \) where \( V_i, r_i \) are defined in (9). Observe that they are minimal sufficient for \( \{ \sigma_\alpha^2, \sigma_\varepsilon^2 \} \) under the model in (8). When \( d = 2 \), the relationship between \( (\sigma_\alpha^2, \sigma_\varepsilon^2) \) and \( (Q_1, Q_2) \) is invertible. This makes fiducial inference for the case \( d = 2 \) quite straightforward and is not considered here. Hereafter we assume \( d > 2 \) which is the more general and challenging case. We rewrite the expressions in (10) as follows.

\[
Q_1 = \frac{(\lambda_1 \sigma_\alpha^2 + \sigma_\varepsilon^2) U_1}{r_1}, \quad Q_2 = \frac{(\lambda_2 \sigma_\alpha^2 + \sigma_\varepsilon^2) U_2}{r_2}, \ldots, \quad Q_d = \frac{(\lambda_d \sigma_\alpha^2 + \sigma_\varepsilon^2) U_d}{r_d}.
\]

(15)

Observe that (15) provide a structural representation for the observable random vector \( Q = (Q_1, \ldots, Q_d) \) in terms of the random vector \( U = (U_1, \ldots, U_d) \) whose distribution is completely
known. We denote realized values of \( Q_i \) and \( U_i \) by \( q_i \) and \( u_i \), respectively, for \( i = 1, \ldots, d \). Solving the first two equations in (15) for \( \sigma^2_\alpha \) and \( \sigma^2_\varepsilon \) gives

\[
\sigma^2_\alpha = \frac{1}{(\lambda_1 - \lambda_2)} \left( \frac{r_1Q_1}{U_1} - \frac{r_2Q_2}{U_2} \right), \quad \sigma^2_\varepsilon = \frac{1}{(\lambda_1 - \lambda_2)} \left( -\frac{\lambda_2r_1Q_1}{U_1} + \lambda_1r_2Q_2 \right). \tag{16}
\]

Therefore the system of equations in (15) is consistent if and only if the values of \( \sigma^2_\alpha \) and \( \sigma^2_\varepsilon \) in (16) also satisfy the remaining equations in (15). This requirement leads to the following set of constraints that must be satisfied by \( q \) and \( u \), the realized values of \( Q \) and \( U \), respectively.

\[
q_j = \frac{u_j}{r_j(\lambda_1 - \lambda_2)} \left( \frac{r_1q_1(\lambda_j - \lambda_2)}{u_1} - \frac{r_2q_2(\lambda_j - \lambda_1)}{u_2} \right) \quad \text{for} \quad j = 3, \ldots, d.
\]

The set-valued function \( R(q, U^*) \) in the fiducial recipe is the set of all \( \sigma^2_\alpha, \sigma^2_\varepsilon \) with \( \lambda_i\sigma^2_\alpha + \sigma^2_\varepsilon > 0 \), \( i = 1, \ldots, d \) for which the equations

\[
q_i = \frac{(\lambda_i\sigma^2_\alpha + \sigma^2_\varepsilon)U^*_i}{r_i}, \quad i = 1, \ldots, d,
\]

are satisfied. The set \( R(q, U^*) \) is nonempty if and only if

\[
q_j = \frac{U^*_j}{r_j(\lambda_1 - \lambda_2)} \left( \frac{r_1q_1(\lambda_j - \lambda_2)}{U^*_1} - \frac{r_2q_2(\lambda_j - \lambda_1)}{U^*_2} \right) \quad \text{for} \quad j = 3, \ldots, d, \tag{17}
\]

and, when (17) holds, the set \( R(q, U^*) \) consists of the single element

\[
\left( \frac{1}{(\lambda_1 - \lambda_2)} \left( \frac{r_1q_1}{U^*_1} - \frac{r_2q_2}{U^*_2} \right), \frac{1}{(\lambda_1 - \lambda_2)} \left( -\frac{\lambda_2r_1q_1}{U^*_1} + \lambda_1r_2q_2 \right) \right).
\]

This leads us to define the random variables \( W_1, \ldots, W_d \) as follows.

\[
W_1 = \frac{1}{(\lambda_1 - \lambda_2)} \left( \frac{r_1q_1}{U^*_1} - \frac{r_2q_2}{U^*_2} \right), \\
W_2 = \frac{1}{(\lambda_1 - \lambda_2)} \left( -\frac{\lambda_2r_1q_1}{U^*_1} + \lambda_1r_2q_2 \right), \quad \text{and} \\
W_j = \frac{U^*_j}{r_j(\lambda_1 - \lambda_2)} \left( \frac{r_1q_1(\lambda_j - \lambda_2)}{U^*_1} - \frac{r_2q_2(\lambda_j - \lambda_1)}{U^*_2} \right), \quad j = 3, \ldots, d.
\]

The fiducial distribution of \( (\sigma^2_\alpha, \sigma^2_\varepsilon) \) is then the same as the conditional distribution of \((W_1, W_2)\) given \( W_3 = q_3, \ldots, W_d = q_d \). Routine calculation shows that the joint density of \( W_1, \ldots, W_d \) is given by

\[
f_W(w_1, \ldots, w_d) = \frac{(\lambda_1 - \lambda_2)(r_1q_1)^{\frac{\lambda_2}{2}}(r_2q_2)^{\frac{\lambda_1}{2}}}{2^{\sum_{i=1}^{d} \frac{\lambda_i}{2}} \Gamma \left( \frac{\lambda}{2} \right)} \left( \lambda_1w_1 + w_2 \right)^{\frac{\lambda_1}{2} + 1} \left( \lambda_2w_1 + w_2 \right)^{\frac{\lambda_2}{2} + 1} \\
\times \exp \left[ -\frac{1}{2} \left( \frac{r_1q_1}{\lambda_1w_1 + w_2} + \frac{r_2q_2}{\lambda_2w_1 + w_2} + \sum_{i=3}^{d} \frac{r_iw_i}{\lambda_iw_1 + w_2} \right) \right] \\
\times \prod_{i=3}^{d} \frac{r_i^{\frac{\lambda_i}{2}}w_i^{\frac{\lambda_i}{2} - 1}}{(\lambda_iw_1 + w_2)^{\frac{\lambda_i}{2}}} \prod_{i=1}^{d} I_{\{\lambda_iw_1 + w_2 > 0\}}.
\]
The fiducial distribution of \((\sigma^2_\alpha, \sigma^2_\varepsilon)\) has therefore the density

\[
f_{W_1, W_2}(w_1, w_2) = \frac{f_W(w_1, w_2, q_3, \ldots, q_d)}{\int \int f_W(w_1', w_2', q_3, \ldots, q_d) \, dw_1' \, dw_2'}.
\]

It follows that the fiducial distribution of \(\sigma^2_\alpha\) is given by

\[
f_{W_1}(w_1) = \frac{\int f_W(w_1, w_2, q_3, \ldots, q_d) \, dw_2}{\int \int f_W(w_1', w_2', q_3, \ldots, q_d) \, dw_1' \, dw_2'}.
\]

Observe that the fiducial distribution of \(\sigma^2_\alpha\) is not unique. A different choice of the two equations used for solving for \(\sigma^2_\alpha\) and \(\sigma^2_\varepsilon\) in (15) will result in different joint density for \(W_1, W_2, \ldots, W_d\) and a different fiducial distribution for \(\sigma^2_\varepsilon\). The nonuniqueness comes from the fact we are conditioning on a set of measure zero since \(P(R(q, U^*)) = 0\). This is related to the well known Borel’s paradox described, for example, in Casella and Berger (2002), Section 4.9.3. We partially resolve this by averaging over all \(\binom{d}{2}\) possibilities for choosing the two equations used for solving \(\sigma^2_\alpha\) and \(\sigma^2_\varepsilon\) to derive the joint density of \(W_1, W_2, \ldots, W_d\). Following this approach we get

\[
f_W(w_1, w_2, \ldots, w_d) = \sum_{i<j} \binom{d}{2} 2^{\sum_{i=1}^{d} \frac{r}{2}} \left( \prod_{i=1}^{d} \Gamma \left( \frac{r_i}{2} \right) \right) \left( \prod_{i=1}^{d} \left( \lambda_i w_1 + w_2 \right)^{r_i+1} \right) \left( \prod_{i=1}^{d} \left( \lambda_i w_1 + w_2 \right)^{r_j+1} \right)
\times \exp \left[ -\frac{1}{2} \left( \frac{r_i q_i}{\lambda_i w_1 + w_2} + \frac{r_j q_j}{\lambda_i w_1 + w_2} + \sum_{k \neq i, k \neq j} \frac{r_k w_k}{\lambda_i w_1 + w_2} \right) \right]
\times \prod_{k \neq i, k \neq j} r_k w_k^{r_k-1} \prod_{i=1}^{d} I(\lambda_i w_1 + w_2 > 0).
\]

The resulting fiducial distribution of \((\sigma^2_\alpha, \sigma^2_\varepsilon)\) has the density given by

\[
f_{W_1, W_2}(w_1, w_2) = C \cdot g(w_1, w_2) \tag{18}
\]

where

\[
g(w_1, w_2) = \left( \sum_{i<j} \frac{(\lambda_i - \lambda_j) q_i q_j}{(\lambda_i w_1 + w_2)(\lambda_j w_1 + w_2)} \right) \left( \exp \left( -\frac{1}{2} \sum_{i=1}^{d} \frac{r_i q_i}{\lambda_i w_1 + w_2} \right) \right) \prod_{i=1}^{d} I(\lambda_i w_1 + w_2 > 0).
\]

and

\[
C^{-1} = \int_{-\infty}^{0} \int_{-\lambda w_1}^{\infty} g(w_1, w_2) \, dw_2 \, dw_1 + \int_{0}^{\infty} \int_{-\lambda w_1}^{\infty} g(w_1, w_2) \, dw_2 \, dw_1.
\]

It follows that the fiducial distribution of \(\sigma^2_\alpha\) is given by

\[
f_{W_1}(w_1) = \begin{cases} C \int_{-\lambda w_1}^{\infty} g(w_1, w_2) \, dw_2 & \text{if } w_1 < 0 \\ C \int_{-\lambda w_1}^{\infty} g(w_1, w_2) \, dw_2 & \text{otherwise}. \end{cases}
\]
Let \( R_{\sigma^2_\alpha, \gamma} \) be the 100\( \gamma \)-percentile of the fiducial distribution of \( \sigma^2_\alpha \). Then a two-sided \( (1 - \alpha) \) 100\% fiducial confidence interval for \( \sigma^2_\alpha \) is given by

\[
\left[ \max(0, R_{\sigma^2_\alpha, \alpha/2}, \max(0, R_{\sigma^2_\alpha, 1-\alpha/2}) \right].
\]

### 3.3 A Fiducial confidence interval for \( \sigma^2_\varepsilon \)

A fiducial distribution for \( \sigma^2_\varepsilon \) can be easily derived from the joint fiducial distribution of \( (\sigma^2_\alpha, \sigma^2_\varepsilon) \) in (18) and is given by

\[
f_{W_2}(w_2) = \begin{cases} 
C \int_{-w_2/\lambda}^{\infty} g(w_1, w_2) \, dw_1 & \text{if } w_2 < 0 \text{ and } \lambda > 0 \\
C \int_{-w_2/\lambda_1}^{\infty} g(w_1, w_2) \, dw_1 & \text{if } w_2 > 0 \\
0 & \text{otherwise.}
\end{cases}
\]

where \( C \) and \( g(w_1, w_2) \) are the same as \( C \) and \( g(w_1, w_2) \) in (18), respectively.

Let \( R_{\sigma^2_\varepsilon, \gamma} \) be the 100\( \gamma \)-percentile of the fiducial distribution of \( \sigma^2_\varepsilon \). Then a two-sided \( (1 - \alpha) \) 100\% fiducial confidence interval for \( \sigma^2_\varepsilon \) is given by

\[
\left[ \max(0, R_{\sigma^2_\varepsilon, \alpha/2}, \max(0, R_{\sigma^2_\varepsilon, 1-\alpha/2}) \right].
\]

### 3.4 A Fiducial confidence interval for \( \rho \)

A fiducial distribution for \( \rho \) can be easily derived from the joint fiducial distribution of \( (\sigma^2_\alpha, \sigma^2_\varepsilon) \) in (18). In fact, we obtain the fiducial density for \( \rho \) as the density of \( X = W_1/(W_1 + W_2) \) given by

\[
f_X(x) = \begin{cases} 
C \int_{-\infty}^{0} g(x, y) \, dy & \text{if } \frac{x}{1-x} < -\frac{1}{\lambda} \text{ and } \lambda > 0 \\
C \int_{0}^{\infty} g(x, y) \, dy & \text{if } \frac{x}{1-x} > -\frac{1}{\lambda_1} \\
0 & \text{otherwise}
\end{cases}
\]

where

\[
g(x, y) = \left( \sum_{i<j} \frac{\lambda_i - \lambda_j}{\lambda_i - 1} q_i q_j \right) \left( \frac{(1-x)(\sum_{i=1}^{d} r_i)^2/|y|}{\prod_{i=1}^{d} ((\lambda_i - 1)xy + y)^2} \right)
\times \exp \left( -\frac{1}{2} \sum_{i=1}^{d} \frac{(1-x)r_i q_i}{\lambda_i - 1} xy + y \right) \prod_{i=1}^{d} I_{\{ (\lambda_i - 1)xy + y > 0 \}},
\]

13
and

\[
C^{-1} = \begin{cases} 
\int_{-\infty}^{1/(1-\lambda_d)} \int_{-\infty}^0 g(x, y) \, dy \, dx + \int_1^\infty \int_{0}^0 g(x, y) \, dy \, dx + \int_1^{1/(1-\lambda_1)} \int_0^\infty g(x, y) \, dy \, dx, & \text{if } \lambda_d > 1 \\
\int_{1/(1-\lambda_d)}^1 \int_{-\infty}^0 g(x, y) \, dy \, dx + \int_1^{1/(1-\lambda_1)} \int_0^\infty g(x, y) \, dy \, dx, & \text{if } \lambda_d = 1 \\
\int_{1/(1-\lambda_d)}^{1/(1-\lambda_1)} \int_{-\infty}^0 g(x, y) \, dy \, dx + \int_1^{1/(1-\lambda_1)} \int_0^\infty g(x, y) \, dy \, dx, & \text{if } 0 < \lambda_1 < 1 \\
\int_{1/(1-\lambda_d)}^{1/(1-\lambda_1)} \int_{-\infty}^0 g(x, y) \, dy \, dx + \int_1^{1/(1-\lambda_1)} \int_0^\infty g(x, y) \, dy \, dx, & \text{if } \lambda_1 = 1 \\
\int_{1/(1-\lambda_d)}^{1/(1-\lambda_1)} \int_{-\infty}^0 g(x, y) \, dy \, dx + \int_1^{1/(1-\lambda_1)} \int_0^\infty g(x, y) \, dy \, dx, & \text{if } \lambda_1 > 1 \text{ and } 0 \leq \lambda_d < 1.
\end{cases}
\]

Let \( R_{\rho, \gamma} \) be the 100\(-\gamma\)-percentile of the fiducial distribution of \( \rho \). Then a two-sided \((1 - \alpha)\)100\% fiducial confidence interval for \( \rho \) is given by

\[
[\max(0, \min(R_{\rho, \alpha/2, 1})), \max(0, \min(R_{\rho, 1-\alpha/2, 1}))].
\] (19)

In the next section we describe the details of a simulation study we conducted to compare the proposed fiducial intervals for \( \sigma_\alpha^2 \), \( \sigma_\varepsilon^2 \) and \( \rho \) with previously proposed methods.

### 4 Simulation Study and Discussion

The coverage probability of a confidence interval on \( \sigma_\alpha^2 \) depends on the design (e.g. number of within group measurements, \( n_1, \ldots, n_a \)) as well as the values of \( \sigma_\alpha^2 \) and \( \sigma_\varepsilon^2 \). The degree of imbalance of the design, in the case of a one-way random effects model, has been quantified by Ahrens and Pincus (1981) using the measure \( \Phi \) defined as

\[
\Phi = \frac{a}{N} \sum_{i=1}^{n_a} 1/n_i = \frac{a \hat{n}}{N}
\]

Note that \( 0 < \Phi \leq 1 \) and that \( \Phi \) equals one if and only if \( n_i \) are all equal. The smaller the value of \( \Phi \) is, the larger is the degree of imbalance. For our simulation study we selected seven different unbalanced patterns shown in Table 2. Patterns 1, 2 and 5 were also considered in Hartung and Knapp (2000). Pattern 4 was also considered in Arendacká (2005). We added the additional patterns 3, 6, and 7 to study the performance of confidence intervals in small sample situations. Without loss of generality, we assumed that \( \mu = 0 \). The values selected for \((\sigma_\alpha^2, \sigma_\varepsilon^2)\) are (0.1, 10), (0.5, 10), (1, 10), (0.5, 2), (1, 1), (2, 0.5), (5, 0.2), and (10, 0.1), where the settings (0.1, 10), (0.5, 2), (1, 1), (2, 0.5), (5, 0.2) were used by Arendacká (2005). Three more settings were added to our study to better investigate the performance of confidence intervals under extremely large and small values of the ratio \( \sigma_\alpha^2/\sigma_\varepsilon^2 \).

For each setting of sample sizes \( n_i \) and values of \((\sigma_\alpha^2, \sigma_\varepsilon^2)\), 3000 independent data sets were generated and two-sided 95\% confidence intervals for \( \sigma_\alpha^2 \) were computed for each method. The methods compared were (a) **BG** interval, (b) **TH** interval, (c) **BE** interval, (d) **HK** interval, (e) **Ar** interval, and (f) **FI** interval. The criteria for judging the performance of the methods are (i) the empirical coverage probabilities and (ii) the average lengths of the confidence intervals. The
normal approximation to the binomial distribution suggests that, when the true coverage probability is 95%(90%), then there is less than a 2.5% chance that the empirical coverage based on 3000 simulations will be less than 94.2%(88.9%) and a 2.5% chance that it will exceed 95.8%(91.1%). Therefore, values for the empirical coverages within the binomial confidence limits may be deemed to maintain the declared coverage levels.

The results of our simulation study are shown in Appendix. The results show that BG procedure is very liberal when the ratio $\eta = \sigma^2_\alpha / \sigma^2_\varepsilon$ is large. The TH procedure is liberal for small values of $\eta$ and very unbalanced designs. This finding agrees with the findings of Burdick and Eickman (1986). The BE procedure is conservative and its behavior for large $\eta$ is similar to that of the TH procedure. The HK procedure becomes more conservative as the value of $\eta$ becomes large.

The Ar procedure appears to always maintain the stated confidence coefficient. The FI interval is conservative when the ratio $\eta$ is less than 1, but maintains the stated confidence coefficient when $\eta$ is greater than or equal to 1.

Comparing average interval lengths, we observe that all the intervals behave very similarly except the BG interval and the FI interval. Although the BG interval has small average lengths, it does not adequately maintain the stated coverage probabilities when $\eta$ is large. Therefore the BG interval is not recommended. When compared with procedures other than the BG procedure, the FI interval always has the smallest average lengths and standard deviations, even when it is conservative. The average lengths of FI intervals are 10% to 25% smaller than the average lengths of other intervals, except BG interval.

Based on the above results, we recommend the FI intervals for $\sigma^2_\alpha$ as the most suitable choice for practical applications.

5 Examples

As noted earlier, a fiducial interval for $\sigma^2_\alpha$, $\sigma^2_\varepsilon$ and $\rho$ is available in the general mixed model (1) with two variance components. In this section we give two examples both of which arise from animal breeding studies. The first example uses a model that might be referred to as a sire model. The degrees of freedom for error is positive and the eigenvalue $\lambda_d$ is zero in this example. The

second example uses a model that may be referred to as a full animal model. All eigenvalues \( \lambda_j, j = 1, \ldots, d \), are positive and hence there are no degrees of freedom available for error.

### 5.1 Sire model

This data set was used in Harville and Fenech (1985) and Burch (1996). The data consist of the birth weight of male lambs which were obtained from five distinct population lines (two control lines and three selection lines). Sixty-two observations were made on progeny of twenty-three rams and each lamb came from a different dam. The age of each dam was recorded as belonging to one of three categories: 1-2 years, 2-3 years, and over 3 years. The fixed effects in this case are population line and age of dam. The random effects are the ram’s (additive) genetic effects (within lines) and error (which includes environmental effects).

The mixed linear model we consider is

\[
Y_{ijkl} = \mu + \alpha_i + \beta_j + \gamma_k(j) + \varepsilon_{ijkl}, \quad i = 1, \ldots, 3, \quad j = 1, \ldots, 5, \quad k = 1, \ldots, 23,
\]

where \( Y_{ijkl} \) is the birthweight of the \( l \)th lamb of the \( k \)th ram in the \( j \)th population line from a dam belonging to the \( i \)th age category. Assume that the ram’s genetic effects \( \gamma_k(j) \) are distributed independently as \( N(0, \sigma^2_{\alpha}) \) and the errors \( \varepsilon_{ijkl} \) are distributed as \( N(0, \sigma^2_{\varepsilon}) \) independently of each other and of the ram’s genetic effects. The quantity \( \mu \) is the general mean, \( \alpha_i \) are fixed effects due to the age group of the dam, and \( \beta_j \) are fixed effects due to the different population lines. The relationship matrix \( A \) is \( I_{56} \).

The number of distinct eigenvalues of \( G = H^T Z A Z^T H \) is \( d = 18 \). The eigenvalues range in magnitude from \( \lambda_1 = 5.087479 \) to \( \lambda_{18} = 0 \). The eigenvalue \( \lambda_{18} = 0 \) with multiplicity \( r_{18} = 37 \), \( \lambda_8 = 2.0 \) with multiplicity \( r_8 = 2 \), and all remaining eigenvalues have a multiplicity of one. The method of moments (MOM) estimates of \( \sigma^2_{\alpha} \) and \( \sigma^2_{\varepsilon} \) are 0.7676 and 2.7631, respectively. The corresponding estimate of \( \rho \) is 0.2174. We refer to this estimate as MOM estimate of \( \rho \). The REML estimates of \( \sigma^2_{\alpha} \) and \( \sigma^2_{\varepsilon} \) are 0.5171 and 2.9616, respectively. The corresponding estimate of \( \rho \) is 0.1486. We refer to this estimate as REML estimate of \( \rho \).

The ANOVA table for this data set is shown in Table 3. Figure 1 shows a plot of the fiducial density of \( \sigma^2_{\alpha} \).

Note that the support of the fiducial density for $\sigma_\alpha^2$, $\sigma_\varepsilon^2$ and $\rho$ might be a proper superset of their natural boundaries. When calculating fiducial confidence intervals, we replace negative confidence bounds with 0 and when a confidence bound for $\rho$ happens to be bigger than 1 we replace it with 1. Table 4 shows the \textbf{Ar} and the \textbf{FI} confidence intervals for $\sigma_\alpha^2$ with 90% and 95% nominal confidence coefficients. Simulated empirical coverages associated with the nominally 90% and 95% confidence intervals for $\sigma_\alpha^2$, along with their average lengths, using MOM and REML estimates of $\sigma_\alpha^2$ and $\sigma_\varepsilon^2$ as their true values, respectively, are shown in Table 5. The results show that the \textbf{FI} method gives shorter confidence intervals for this data set. Comparing the average lengths of the intervals, the \textbf{FI} confidence interval has smaller average lengths, despite being more conservative than the \textbf{Ar} confidence interval. In summary, the \textbf{FI} procedure performs better than the \textbf{Ar} method for this lamb birth-weight data set.

95% confidence intervals for $\sigma_2^2$, along with their average lengths, using MOM and REML estimates of $\sigma_2^2$ and $\sigma_2^2$ as their true values, respectively. The results show that the fiducial interval has smaller average length, although FI method gives a slightly wider confidence interval for this data set.

Figure 3: Fiducial density plot for $\rho$ for the lamb birth-weight data.

Figure 3 shows a plot of the fiducial density of $\rho$ for this data set. Note that the range of $\rho$ is $1/(1 - \lambda_1), i.e., (-0.2446, 1)$. Observe that there does not exist an unbiased BI confidence interval for $\rho$. In this case, we take $k = 17$ in the BI procedure which gives us the pivotal quantity having the closest "balance" between the numerator and the denominator degrees of freedom where $r_{18} = 37$ and $\sum_{i=1}^{17} r_i = 18$.

Table 8 shows the FI confidence interval and the BI confidence interval for $\rho$ with 90% and 95% nominal confidence coefficients. Table 9 shows empirical coverages corresponding to these intervals along with their average lengths. These simulations are conducted with the MOM and REML estimates of $\sigma^2_\alpha$, $\sigma^2_\epsilon$ and $\rho$, respectively, as their true values. The results show that the FI method gives a shorter confidence interval for $\rho$ in this data set. Comparing the average lengths of the intervals, the FI confidence interval has a smaller average length although it is more conservative than the BI confidence interval. In summary, the FI procedure performs better than the BI method for this lamb birth-weight data set.

5.2 Full animal model

This data was used in Burch (1996) and Burch and Iyer (1997). Data were obtained on one hundred and seventy-one yearling bulls from a Red Angus seed stock in Montana. A trait of interest was the loin eye (i.e., ribeye) muscle area measured in square inches. Ultrasound techniques were used to obtain these measurements. The fixed effect was age of dam, which belongs to one of five categories: 2 years, 3 years, 4 years, 5-9 years, and 10 or more years. The random effects are animal’s (additive) genetic effect and error. The mixed linear model being considered can be represented by

$$Y = X\beta + Zu + \varepsilon,$$

where $Y$ is a $171 \times 1$ vector of observable random variables, $X$ is a $171 \times 5$ design matrix, $\beta$ is a $5 \times 1$ vector of unknown parameters, $Z = I_{171}$, and $u$ and $\varepsilon$ are vectors of unobservable random
variables of size $171 \times 1$. The relationship matrix $A$ was determined using a recursive method given in Henderson (1976). This means $Var(u) = \sigma^2 \alpha A$.

The number of distinct eigenvalues of $G = H^T Z AZ^T H$ is $d = 165$. Eigenvalues range in magnitude from $\lambda_1 = 8.5692472$ to $\lambda_{165} = 0.5656916$. Except for $\lambda_{105} = 0.6718750$ having $r_{105} = 2$, all eigenvalues have a multiplicity of one. The REML estimates of $\sigma^2 \alpha$ and $\sigma^2 \varepsilon$ are 0.2994 and 2.6539, respectively. The corresponding estimate of $\rho$ is 0.1014. We refer to this estimate as REML estimate of $\rho$.

Figure 6: Fiducial density plot for $\rho$ for the loin-eye data.

$\sigma^2_\varepsilon$ using REML estimates of $\sigma^2_\alpha$ and $\sigma^2_\varepsilon$ as their true values.

Figure 6 shows the plot of the fiducial density for $\rho$ for this data set. The support of this density is

$$\left\{ \rho : \rho \in \left( \frac{1}{1 - \lambda_1}, 1 \right) \cup \left( 1, \frac{1}{1 - \lambda_d} \right) \right\},$$

i.e., $\left\{ \rho : \rho \in (-0.1321, 1) \cup (1, 2.3025) \right\}$. The BI pivotal quantity that results in an unbiased confidence interval corresponds to $k = 83$. In this case, $\sum_{i=1}^{83} r_i = \sum_{j=84}^{165} r_j = 83$. We will use this unbiased confidence interval as the BI confidence interval in the following discussion. It is interesting to note that the BI confidence interval covers the entire parameter space. Inverting the pivotal quantity in (14) results in a confidence interval whose endpoints fall outside of the parameter space.
Harville and Fenech (1985) attribute this to lack of sufficient information in the data about the parameter of interest in such cases.

Table 14 shows the FI confidence interval and the BI confidence interval for \( \rho \) with 90% and 95% nominal confidence coefficients. Table 15 shows the empirical coverages of these interval procedures for \( \rho \) using REML estimates of \( \sigma^2_\alpha \), \( \sigma^2_\varepsilon \) and \( \rho \) as their true values, respectively. The results show that the FI method leads to a shorter confidence interval for \( \rho \) in this data set. Comparing the empirical coverages, the FI confidence interval is more conservative than the BI confidence interval.

In summary, the FI method performs better than the BI method for this loin-eye data set.

6 Asymptotic exactness of fiducial intervals

When deriving the FI procedure we considered the following structural equations for \( \sigma^2_\alpha \) and \( \sigma^2_\varepsilon \).

\[
Q_1 = \frac{\sigma^2_\alpha}{r_1}(\lambda_1 - \lambda_2)U_1, \quad Q_2 = \frac{\sigma^2_\alpha}{r_2}(\lambda_1 - \lambda_2)U_2, \quad \ldots, \quad Q_d = \frac{\sigma^2_\alpha}{r_d}(\lambda_1 - \lambda_2)U_d
\]

Here \( \lambda_i \) is an eigenvalue of \( G \) in (8), \( r_i \) its multiplicity and \( U_i \) are independent random variables with \( \chi^2 \)-distribution on \( r_i \) degrees of freedom, respectively, for \( i = 1, \ldots, d \). The fiducial distribution based on this structural equation was then derived to be a constant multiple of

\[
g(w_1, w_2) = \left( \sum_{i<j} \frac{(\lambda_i - \lambda_j)q_iq_j}{(\lambda_i w_1 + w_2)(\lambda_j w_1 + w_2)} \right) \left( \frac{\exp\left(-\frac{1}{2} \sum_{i=1}^{d} \frac{r_iq_i}{\lambda_i w_1 + w_2}\right)}{\prod_{i=1}^{d} (\lambda_i w_1 + w_2)^{\frac{r_i}{2}}} \right) \prod_{i=1}^{d} I_{(\lambda_i w_1 + w_2 > 0)}. \quad (20)
\]

Hannig (2006) has proved that this fiducial distribution leads to asymptotically correct frequentist inference if \( d = 3 \) and \( r_i \to \infty \). His method can be easily generalized to any \( d \) fixed. However, this
is not sufficient for many applications, where we have a large number of different eigenvalues with multiplicities that are relatively small, such as the loin-eye data set discussed above. We now prove that under some natural conditions related to the Fisher’s information the fiducial distribution leads to asymptotically correct frequentist inference even when $d \to \infty$.

**Theorem 1.** Denote $n = \sum_{j=1}^{d} r_j$ and assume that the limits

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{d} \frac{\lambda_j^k r_j}{(\lambda_j \sigma_\alpha^2 + \sigma_\varepsilon^2)^2} = m_k \quad \text{for} \quad k = 0, 1, 2$$

are such that the matrix

$$\Sigma = \begin{pmatrix} m_0 & m_1 \\ m_1 & m_2 \end{pmatrix}$$

is positive definite. Then the frequentist coverage probability of the $(1 - \alpha)$ equal tailed fiducial interval based on the joint fiducial distribution of $(\sigma_\alpha^2, \sigma_\varepsilon^2)$ approaches the stated value as $n \to \infty$.

**Proof.** We will use the ideas contained in the proof of Theorem 1 of Hannig (2006). Define the random vectors

$$S = \left( \sum_{i=1}^{d} \frac{r_i Q_i}{(\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2)^2}, \sum_{i=1}^{d} \lambda_i r_i Q_i \right),$$

$$t = \left( \sum_{i=1}^{d} \frac{r_i}{\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2}, \sum_{i=1}^{d} \lambda_i r_i \right).$$

We will show that $(S - t)/\sqrt{n}$ converges in distribution to a normal random vector.

To this end assume without loss of generality that $r_i = 1$ for all $i$, possibly repeating some eigenvalues several times. We can then write

$$S - t = \left( \sum_{i=1}^{n} \frac{(U_i - 1)}{\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2}, \sum_{i=1}^{n} \frac{\lambda_i (U_i - 1)}{\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2} \right),$$

where $U_i$ are i.i.d. chi-squared random variables with one degree of freedom. To prove the convergence we will use the Cramèr-Wold device. Fix $a, b$ and denote

$$c = \max_{j=1, \ldots, n} \frac{(a + b \lambda_j)^2}{(\lambda_j \sigma_\alpha^2 + \sigma_\varepsilon^2)^2}.$$ 

By our assumptions $c/n \to 0$. Next, we verify the Lindeberg-Feller condition

$$\lim_{n \to \infty} \sum_{i=1}^{n} E \left[ \frac{(a + b \lambda_i)^2 (U_i - 1)^2}{n(\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2)^2}; \frac{(a + b \lambda_j)^2}{n(\lambda_j \sigma_\alpha^2 + \sigma_\varepsilon^2)^2} \varepsilon < \frac{(a + b \lambda_i)^2 (U_i - 1)^2}{n(\lambda_i \sigma_\alpha^2 + \sigma_\varepsilon^2)^2} \right]$$

$$\leq \lim_{n \to \infty} E \left[ c(U_i - 1)^2; (a^2 m_0 + 2abm_1 + b^2 m_2) \frac{\varepsilon}{2} < c(U_i - 1)^2 \right]$$

$$= 0.$$
Thus we conclude \((S - t)/\sqrt{n} \overset{D}{\to} H = (H_1, H_2) \sim N(0, 2\Sigma)\). By Skorokhod’s representation theorem (Billingsley, 1995) this convergence can be taken a.s. The a.s. convergence is assumed in the rest of the proof.

We will now investigate the distribution of \(\sqrt{n}(R(x, \sigma^2) - (\sigma^2_x, \sigma^2_S))\). The density of this random variable is a constant multiple of \(r(z_1, z_2) = g(\sigma_x^2 + z_1/\sqrt{n}, \sigma_S^2 + z_2/\sqrt{n})\) where \(g\) is defined in (20). For future reference denote this constant \(C_n\), i.e., the density is \(C_n^{-1}r(z_1, z_2)\). Set \(w_1 = \sigma_x^2 + z_1/\sqrt{n}\) and \(w_2 = \sigma_S^2 + z_2/\sqrt{n}\) and consider

\[
\log r(z_1, z_2) = -\frac{1}{2} \sum_{i=1}^{d} r_i \left( \frac{q_i}{\lambda_i w_1 + w_2} + \log(\lambda_i w_1 + w_2) \right) + \log \left( \frac{d}{2} \sum_{i<j} \frac{(\lambda_i - \lambda_j) q_i q_j}{(\lambda_i w_1 + w_2)(\lambda_j w_1 + w_2)} \right). \tag{21}
\]

Applying Taylor series to each term of the the first sum in (21) we get

\[
\sum_{i=1}^{d} r_i \left( \frac{q_i}{\lambda_i w_1 + w_2} + \log(\lambda_i w_1 + w_2) \right) = -n^{-1/2}z_1 \sum_{i=1}^{d} \left( \frac{r_i q_i}{(\lambda_i \sigma^2_x + \sigma^2_S)^2} - \frac{r_i}{\lambda_i \sigma^2_x + \sigma^2_S} \right)
- n^{-1/2}z_2 \sum_{i=1}^{d} \left( \frac{\lambda_i r_i q_i}{(\lambda_i \sigma^2_x + \sigma^2_S)^3} - \frac{\lambda_i r_i}{2(\lambda_i \sigma^2_x + \sigma^2_S)^2} \right)
+ n^{-1}z_1^2 \sum_{i=1}^{d} \left( \frac{\lambda_i r_i q_i}{(\lambda_i \sigma^2_x + \sigma^2_S)^3} - \frac{\lambda_i r_i}{2(\lambda_i \sigma^2_x + \sigma^2_S)^2} \right)
+ \sum_{i=1}^{d} r_i \left( \frac{q_i}{\lambda_i \sigma^2_x + \sigma^2_S} + \log(\lambda_i \sigma^2_x + \sigma^2_S) \right) + o_{as}(1). \tag{22}
\]

As noted above, the first two terms on the right hand side of (22) converge a.s. as \(n \to \infty\) to \(-z_1H_1 - z_2H_2\). By Slutsky’s theorem the next three terms converge a.s. to \(z_1^2 m_0 + 2z_1 z_2 m_1 + z_2^2 m_2\).

Similarly set

\[ L_n = \left( \frac{d}{2} \right)^{-1} \sum_{i<j} \frac{(\lambda_i - \lambda_j) q_i q_j}{(\lambda_i \sigma^2_x + \sigma^2_S)(\lambda_j \sigma^2_x + \sigma^2_S)} \]

and notice

\[
\log \left( \frac{d}{2} \sum_{i<j} \frac{(\lambda_i - \lambda_j) q_i q_j}{(\lambda_i w_1 + w_2)(\lambda_j w_1 + w_2)} \right) - \log(L_n) \to 0 \quad a.s.
\]

Define

\[
K_n = \frac{\exp \left( \frac{1}{2} \sum_{i=1}^{d} r_i \left( \frac{q_i}{\lambda_i \sigma^2_x + \sigma^2_S} + \log(\lambda_i \sigma^2_x + \sigma^2_S) \right) - \frac{1}{4} H^T \Sigma^{-1} H \right)}{2\pi L_n \sqrt{\det(2\Sigma^{-1})}}
\]

26
and notice that
\[
h(z_1, z_2) = \lim_{n \to \infty} K_n r(z_1, z_2)
= K \exp \left\{ -\frac{1}{4} \left( z_1^2 m_0 + 2z_1z_2 m_1 + z_2^2 m_2 - 2z_1 H_1 - 2z_2 H_2 \right) \right\} \quad \text{a.s.}
\]

Here the constant $K$ is chosen so that $h(z_1, z_2)$ integrates to one. Notice that conditionally on $H$, $h(z_1, z_2)$ is a density of a multivariate normal distribution $N(\Sigma^{-1}H, 2\Sigma^{-1})$. We also notice that unconditionally $\Sigma^{-1}H \sim N(0, 2\Sigma^{-1})$.

Recall that the density of $\sqrt{n}(R(\sigma^2_\alpha, \sigma^2_\varepsilon) - (\sigma^2_\alpha, \sigma^2_\varepsilon))$ is $C_n^{-1} r(z_1, z_2)$. Furthermore, the functions $\sqrt{\det(2\Sigma^{-1})} K_n r(\sqrt{2\Sigma^{-1}/2} z + \Sigma^{-1}H)$ are dominated by $C(1 + z_1^2 + z_2^2)^{-1}$ for $C$ large enough. Thus the Lebesgue dominated convergence theorem, the fact that densities integrate to one, and Fatou’s lemma imply that $K_n C_n \to 1$. We conclude that the density $C_n^{-1} r(z_1, z_2)$ converges to the density of $N(\Sigma^{-1}H, 2\Sigma^{-1})$.

This verifies the crucial assumption 1.2 of Hannig (2006). Also, the equal tailed region satisfies the assumption 1.3 of Hannig (2006). The rest of the proof is identical to the proof of Theorem 1 in Hannig (2006).

Remark 1. It is worth noting that the Fisher information matrix $F$ for $(\sigma^2_\alpha, \sigma^2_\varepsilon)$ based on $Q_i$, $i = 1, \ldots, d$, is the 2 by 2 matrix whose $(j, k)$ element is given by
\[
\sum_{i=1}^{d} \frac{r_i \lambda^{j+k-2}_i}{2(\lambda_i \sigma^2_\alpha + \sigma^2_\varepsilon)^2}
\]
for $j, k = 1, 2$. Hence the conditions of the theorem is a statement of the requirement that $\frac{1}{n} F$ converge to a positive definite matrix as $n \to \infty$.

7 Closing Remarks

In this paper, we proposed confidence interval procedures for $\sigma^2_\alpha$, $\sigma^2_\varepsilon$ and $\rho$ in a two component mixed effects linear model using the fiducial approach. A simulation study was carried out to compare the proposed confidence interval for $\sigma^2_\alpha$ with five other confidence intervals from the literature, the proposed confidence interval for $\sigma^2_\varepsilon$ with exact confidence interval, and the proposed confidence interval for $\rho$ with the method due to Burch and Iyer (1997). The results of a simulation study show that the proposed fiducial intervals for $\sigma^2_\alpha$ are satisfactory in terms of coverage probability. Although they are conservative for small values of the variance ratio $\eta = \sigma^2_\alpha / \sigma^2_\varepsilon$, they have the smallest average interval lengths among all confidence intervals. Two examples in the context of animal breeding applications are given to illustrate the use of the proposed procedures. The results confirm that the fiducial intervals can be recommended for practical use over the methods previously discussed in the literature.

Fiducial methods have a rich history beginning from the 1930s. While these methods failed to become part of mainstream statistics, recently there has been a resurgence of these methods either
under the label of fiducial inference or as generalized inference. Details of connections between
fiducial inference and generalized inference may be found in Hannig et. al (2006). An important
point to note is that, because the fiducial method is very generally applicable, the methods discussed
in this paper, in principle, can be straightforwardly extended to more complex mixed linear models
with multiple variance components. However, computational details need to be sorted out. This is
ongoing research.
## A Numerical Results from the Simulation Study
