

The Use of Survey Weights in Regression Modelling

Chris Skinner

London School of Economics and Political Science

(with Jae-Kwang Kim, Iowa State University)

Colorado State University, June 2013

Weighting in Regression Modelling

Established

- whether to weight
- implementation in practice

Modern developments

- adapting to new modelling settings
- new ways of constructing (**modifying**) weights (for particular models)

Modifying Weights

to retain benefits of weights, while mitigating disadvantages

Pros and Cons of Weighting

Pros

- to avoid **bias** from **informative sampling**, when inclusion probabilities π_j unequal
(note: other approaches can also do this, e.g. sample likelihood, Pfeffermann, 2011)
- to protect against **model misspecification**
- to make efficient use of population-level information

Cons

- variance inflation from unequal inclusion probabilities

Motivating Application: Cross-National Comparative Survey Analysis

Common for π_j to vary, especially between countries.

“population sizes of countries have a tremendous, thousand-fold range; whereas sample sizes tend to be made more constant in order to obtain similar errors for national means” Kish (1994)

But with great variation in π_j , loss of efficiency from π_j^{-1} weighting may be high.

Want to retain **consistency** of weighted estimation while avoiding too much **inflation of variance**.

Outline

1. First kind of weight modification - theory
2. Application to European Social Survey
3. Second kind of weight modification - theory
4. Simulation study

Model

Population $U = \{1, 2, \dots, N\}$

Regression model $f(y_j; \mathbf{x}_j, \boldsymbol{\beta})$

Score $\mathbf{u}_j(y_j; \mathbf{x}_j, \boldsymbol{\beta}) = \frac{\partial \log f(y_j; \mathbf{x}_j; \boldsymbol{\beta})}{\partial \boldsymbol{\beta}}$

write $\mathbf{u}_j(\boldsymbol{\beta}) = \mathbf{u}_j(y_j; \mathbf{x}_j, \boldsymbol{\beta})$

Mean score model: $E_m\{\mathbf{u}_j(\boldsymbol{\beta})\} = \mathbf{0}$, $j = 1, 2, \dots, N$

Census Parameter

β_U solves

$$\sum_{j=1}^N \mathbf{u}_j(\beta) = \mathbf{0}.$$

Kish and Frankel (1974), Godambe and Thompson (1986) say β_U of interest even if model fails.

But is it really always the appropriate pseudo-parameter when model fails? E.g. Scott and Wild (2002, 2003), Skinner (2003)

Sampling

Sample

$$s \subset U$$

Sample indicator variable

$$I_j = 1 \quad \text{if } j \in s$$
$$I_j = 0 \quad \text{if } j \notin s,$$

(Unweighted) Sample Estimating Equations

$\hat{\beta}$ solves

$$\sum_{j=1}^N l_j \mathbf{u}_j(\beta) = \mathbf{0}.$$

design-model consistent if $E_m E_p \{ l_j \mathbf{u}_j(\beta) \} = \mathbf{0}$, $j = 1, 2, \dots, N$

in particular, if l_j and Y_j independent (given \mathbf{x}_j) **noninformative sampling**

Weighted Sample Estimating equations

$\hat{\beta}_w$ solves

$$\sum_{j=1}^N l_j w_j \mathbf{u}_j(\beta) = \mathbf{0}.$$

design-model consistency condition:

$$E_m E_p \{ l_j w_j \mathbf{u}_j(\beta) \} = \mathbf{0}, j = 1, 2, \dots, N$$

Design Consistency

$\hat{\beta}$ design consistent for β_U if

$$E_p \left\{ \sum_{j=1}^N I_j w_j \mathbf{u}_j(\beta) \right\} = \sum_{j=1}^N \mathbf{u}_j(\beta) \quad \text{for arbitrary } y_j \text{ and } \beta$$

so $E_p(I_j w_j) = 1$ design consistency condition

Design Weights

Hence $w_j = \pi_j^{-1}$, Horvitz-Thompson weight or design weight, if w_j is not sample-dependent

Godambe and Thompson (1986, Theorem 1)

Horvitz-Thompson weighted estimation equations optimal within broader class of sample estimating equations (which give design consistent estimation of β_U)

Widening Class of Weights

But design consistency condition may not be appropriate scientifically. We drop it to enable us to improve efficiency.

Now require only design-model consistency condition, but do assume mean score model holds.

design consistency condition \Rightarrow design-model consistency condition

So class of possible weights is widened

First Kind of Weight Modification

Modification by function of covariates.

Class of **modified weights** $w_j = d_j q_j$, where $d_j = \pi_j^{-1}$ and $q_j = q(\mathbf{x}_j)$ (not sample dependent)

- meets design-model consistency condition if mean score model holds.
- will generally not meet design-consistency condition unless $q_j \equiv \text{constant}$

Optimization Problem

to determine function $q(\cdot)$ which minimises $var_{mp}(\hat{\beta}_w)$

$$var_{mp}(\hat{\beta}_w) = \mathbf{J}(\beta)^{-1} var_{mp} \left\{ \sum_{j=1}^N w_j l_j \mathbf{u}_j(\beta) \right\} \mathbf{J}(\beta)^{-1}$$

where

$$\mathbf{J}(\beta) = E_{mp} \left\{ \sum_{j=1}^N l_j w_j \frac{\partial \mathbf{u}_j(\beta)}{\partial \beta} \right\}$$

Approximations/Assumptions

- observations for different units are approximately independent
- **generalized linear model** so that $\mathbf{u}_j(\boldsymbol{\beta}) = e_j \mathbf{x}_j$

$$\text{var}_{mp}(\widehat{\boldsymbol{\beta}}_w) \approx \left\{ \sum_{j=1}^N q_j E_m(e_j^2) \mathbf{x}_j \mathbf{x}_j^T \right\}^{-1} \sum_{j=1}^N q_j^2 E_m(d_j e_j^2) \mathbf{x}_j \mathbf{x}_j^T \left\{ \sum_{j=1}^N q_j E_m(e_j^2) \mathbf{x}_j \mathbf{x}_j^T \right\}^{-1}$$

(Approximately) Optimal Solution

$$q_j \propto \frac{E_m(e_j^2 | \mathbf{x}_j)}{E_m(d_j e_j^2 | \mathbf{x}_j)}$$

Equivalent to Fuller (2009, Sect 6.3.2) for linear regression model

Requires fitting of model to $E_m(d_j e_j^2 | \mathbf{x}_j)$

Estimating $q(\cdot)$

e_j is scaled version of residual $y_j - E_m(Y_j | \mathbf{x}_j)$

As a first approximation, suppose d_j and e_j^2 are uncorrelated and set $q_j = 1/E_m(d_j | \mathbf{x}_j)$

And thus $w_j = d_j q_j = d_j / E_m(d_j | \mathbf{x}_j)$

Design weight standardized for its dependence on \mathbf{x}_j

Different from Pfeffermann and Sverchkov (1999, 2003)

$$q_j \propto 1/E_m(d_j | I_j = 1, \mathbf{x}_j)$$

Will discuss estimation of $E_m(d_j | \mathbf{x}_j)$ later

Application: Voter Turnout in Europe

- European Social Survey Round 1 - 2002
- subsample of 2621 people aged 18-24 in 19 European countries, providing data on variables relating to political interest and civic duty
- analysis similar to Fieldhouse, Tranmer and Russell (2007) *European J. Political Research*

Logistic Regression Analysis

$y = 1$, if voted in last national election in country
 $= 0$, otherwise

x variables for rational choice model, including

political efficacy - principal components of questions measuring extent to which respondents think they can understand and influence politics

system benefits - principal components of respondent's feelings of civic duty

Estimated Coefficients of Logistic Regression

variable	unweighted	s.e.	weighted	s.e
political efficacy 1	0.27	0.05	0.25	0.08

has partner	-0.07	0.12	-0.05	0.19
has dependent child	-0.28	0.16	-0.46	0.23
born in country	0.74	0.17	1.20	0.30

Test for Informative Sampling

Augment model by adding interactions between weight and x variables.

Test whether coefficients of new variables are all 0

Wald test $F(14, 2607) = 2.0$, $p = 0.015$.

Conclude significant effect of weighting.

DuMouchel and Duncan (1983), Fuller (2009)

Test as Diagnostic for Misspecification

- informative sampling **may** indicate omitted variable in model
- are there variables which explain π_j which could be included in model?

Sample Selection

- separate sampling in different countries
- sampling schemes vary according to different sampling frames, e.g.
 - lists of residents
 - lists of households
 - lists of addresses

Respecified Model

- major variation in design weights between countries
- introduce country dummy variables in model
- scientifically reasonable, since aim is to study variations in turnout of young people in context of country variation

Variable	Initial model		New model	
	unweighted	weighted	unweighted	weighted
political efficacy 1	0.27	0.25	0.27	0.28
political efficacy 2	0.15	0.13	0.17	0.18
closeness of contest (%)	0.03	0.06	0.05	0.05
Partisanship	0.41	0.48	0.59	0.78
closeness*partnership	0.03	0.01	0.00	0.03
collective benefits	0.02	0.04	0.06	0.10
system benefits 1	0.31	0.35	0.31	0.31
system benefits 2	0.03	0.11	0.06	0.06
is female	0.16	0.14	0.14	0.12
belongs to ethnic minority	-0.65	-0.31	-0.67	-0.34
has partner	-0.07	-0.05	-0.05	0.02
has dependent child	-0.28	-0.46	-0.22	-0.57
born in country	0.74	1.20	0.66	1.14

Results for Respecified Model

- effect of weighting reduced
- no longer significant
- little sense in attempting to respecify model further to include within country design variables, since such variation in designs between countries

Standard Errors

Variable	Unweighted	Weighted
political efficacy 1	0.05	0.08
political efficacy 2	0.06	0.09
closeness of contest (%)	0.02	0.02

closeness*partnership	0.02	0.02
collective benefits	0.06	0.09
system benefits 1	0.04	0.07
system benefits 2	0.05	0.07
is female	0.10	0.14
belongs to ethnic minority	0.22	0.37
has partner	0.13	0.22
has dependent child	0.16	0.26
born in country	0.18	0.30

Within Country Weights as Modified Weights

- Recall modified weight: $w_j = d_j q_j = d_j / E_m(d_j | \mathbf{x}_j)$
- Let $\mathbf{x}^{(1)}$ be vector of country dummy variables, subvector of \mathbf{x}
- Simplify $E_m(d_j | \mathbf{x}_j)$ to $E_m(d_j | \mathbf{x}_j^{(1)})$
- Weighting with $d_j / E_m(d_j | \mathbf{x}_j^{(1)})$ still consistent - achieves most of efficiency gain?
- Estimate $E_m(d_j | \mathbf{x}_j^{(1)})$ by design-weighted mean of design weights $\bar{d}_{c(j)}$ for country $c(j)$
- $d_j / \bar{d}_{c(j)}$ is **within country weight**

Standard Errors

Variable	Unweighted	Within country	Design weights
political efficacy 1	0.05	0.05	0.08
political efficacy 2	0.06	0.06	0.09

born in country	0.18	0.20	0.30

Within Country Weighting

- consistent estimation, provided dependence of y on countries correctly specified in model
- protects against bias from informative selection within countries (non-significant test may lack power)
- avoids inflation of standard errors
- may give consistent estimation for more suitable pseudo-parameter under model misspecification?

Return to Theory

Widening Class of Weights Further

Still assume design-model consistency condition and mean score model holds. Want to minimize

$$\text{var}_{mp}(\hat{\beta}_w) = \mathbf{J}^{-1} \text{var}_{mp} \left\{ \sum_{j=1}^N w_j l_j \mathbf{u}_j(\beta) \right\} \mathbf{J}^{-1}$$

Write

$$\text{var} \left\{ \sum_{j=1}^N w_j l_j \mathbf{u}_j(\beta) \right\} =$$

$$\text{var} \left\{ \sum_{j=1}^N E(w_j | y_j, \mathbf{x}_j, l_j) l_j \mathbf{u}_j(\beta) \right\} + E \left\{ \text{var} \left(\sum_{j=1}^N w_j l_j \mathbf{u}_j(\beta) \mid y_j, \mathbf{x}_j, l_j \right) \right\}$$

Second Kind of Weight Modification

Consistency unaffected if $E(w_j | y_j, \mathbf{x}_j, l_j)l_j = E(d_j | y_j, \mathbf{x}_j, l_j)l_j$

Variance minimized if $\text{var}(w_j | y_j, \mathbf{x}_j, l_j) = 0$

Achieved by setting

$$\begin{aligned}w_j &= E(d_j | y_j, \mathbf{x}_j, l_j = 1)q(\mathbf{x}_j) \\ &\equiv \tilde{d}_j q(\mathbf{x}_j)\end{aligned}$$

modify d_j to \tilde{d}_j , smooths noise in weights unrelated to y_j given \mathbf{x}_j

c.f Beaumont (2008) **weight smoothing**

Chaudhuri et al. (2010), Pfeiffermann (2011) (conditional)
empirical likelihood

Weight Smoothing in Descriptive Surveys

$$T = \sum_j y_j$$

Horvitz-Thompson estimator $\hat{T}_{HT} = \sum_j l_j d_j y_j$

Smoothed Horvitz-Thompson estimator $\hat{T}_{SHT} = \sum_j l_j \tilde{d}_j y_j$

where $\tilde{d}_j \equiv E_{mp}(d_j \mid y_j, l_j = 1)$

$$E_{mp}(\hat{T}_{HT}) = E_{mp}(\hat{T}_{SHT}) = T$$

$$V_{mp}(\hat{T}_{HT}) \geq V_{mp}(\hat{T}_{SHT})$$

Weight Smoothing in Regression

$$w_j = \tilde{d}_j q(\mathbf{x}_j)$$

where $\tilde{d}_j \equiv E(d_j \mid y_j, \mathbf{x}_j, l_j = 1)$

optimal choice

$$q_j \propto \frac{E_m(e_j^2 \mid \mathbf{x}_j)}{E_m(\tilde{d}_j e_j^2 \mid \mathbf{x}_j)}$$

Auxiliary Weight Model(s)

$$\tilde{d}_j = E(d_j \mid y_j, \mathbf{x}_j, l_j = 1) = \tilde{d}(y_j, \mathbf{x}_j; \phi)$$

E.g. $\tilde{d}(y_j, \mathbf{x}_j; \phi) = 1 + \exp(-\phi_1 \mathbf{x}_j - \phi_2 y_j)$

q_j depends on $E(\tilde{d}_j e_j^2 \mid \mathbf{x}_j)$

Iterative estimation of β and ϕ Kim and Skinner (2013)

See also Beaumont (2008), Pfeiffermann (2011)

Variance Estimation

- first weight modification
 - replacement of $q(\mathbf{x}_j)$ by $q(\mathbf{x}_j; \hat{\alpha})$ does not affect asymptotic variance
 - consistent variance estimation by treating weights $d_j q_j$ as fixed
- second weight modification
 - replacement of \tilde{d}_j by $\tilde{d}(y_j, \mathbf{x}_j; \hat{\phi})$ does affect asymptotic variance
 - variance estimation does need take account of error in estimating ϕ
 - Kim and Skinner (2013) give linearization variance estimator

Simulation Study

$$y_j = \beta_0 + \beta_1 \mathbf{x}_j + e_j$$

$$\pi_j = \frac{nk_j}{\sum_{i \in U} k_i}, \quad k_j = \frac{1}{1 + \exp(2.5 - 0.5z_j)}, \quad z_j \sim N(1 + y_j, 0.5^2)$$

Poisson and Chao (1982) sampling

Pfeffermann-Sverchkov $q_j = 1/E(d_j | I_j = 1, \mathbf{x}_j)$

Our first modification $q_j = \frac{E_m(e_j^2 | \mathbf{x}_j)}{E(d_j e_j^2 | \mathbf{x}_j)}$

Simulation Standard Errors - Intercept

Weight	Model A	Model B
Design	1.85	1.28
Pfeffermann-Sverchkov	1.66	1.27
Our first modification	1.65	1.26
Smoothed design	1.81	1.24
Smoothed P-S	1.63	1.24
Our combined modification	1.63	1.22

Simulation Standard Errors - Slope

Weight	Model A	Model B
Design	0.782	1.24
Pfeffermann-Sverchkov	0.637	1.21
Our first modification	0.637	1.21
Smoothed design	0.756	1.21
Smoothed P-S	0.623	1.20
Our combined modification	0.623	1.18

Summary

Both weight modifications offer efficiency gains, assuming (mean score) model holds.

First weight modification offers:

- consistency under misspecification of $q(x)$
- no need to modify variance estimation approach

Smoothing requires:

- correct specification of $E(d_j | y_j, \mathbf{x}_j, l_j = 1)$ for consistency
- modification of variance estimation approach

In both cases, consider whether implied pseudoparameter under misspecification is scientifically reasonable.
